With this book the author makes the subject of spectrum analysis understandable to a wide audience, including those with a solid background in general signal processing and those without such background.

Since speech signal is time-varying, the analysis should be a time-frequency analysis, which is quite different from the context of our 532 course.

In this approach, the speech signal is first subjected to a sequence of difference/sum filtering. Then counts of zero crossings are calculated over short overlapped frames to obtain a sequence of counts. This sequence represents the dominant frequency components of the speech signal over the analysis frames.

In theory, Fourier theorem states that a signal is composed of a number of sinusoidal signals. Analyzing the amplitude, frequency, and phase of these sinusoidal signals is referred to as the frequency spectrum analysis of the signal. To extract these parameters, the signal is filtered, digitized, and Fourier transformed to the frequency domain.
